Forming - Results	72
Cementing - Results	73-74

## INTRODUCTION

### FOREWARD

With the advent of higher performance aircraft designs there has been a definite requirement for transparent materials for aircraft glazing use with improved properties over those existant in materials available during World War II.

With the above problem in mind the AIA - ARTC sought to affect some improvement in transparent materials for use as canopies, windows and domes made of transparent plastic materials of both the monolithic and laminated type and for pressurized and non-pressurized applications. The W-38 subcommittee was subsequently established for that purpose.

The initial objectives of the W-38 subcommittee were as follows:

- a. Assemble and issue all available test information on present transparent monolithic materials.
- b. Establish and issue a list of aircraft industry requirements for improved transparent materials.

On August 9, 1950 the subcommittee completed and released an AIA document entitled "The Summary of the Properties of Transparent Plastic Aircraft Enclosure Materials." This information was released to the services, the material suppliers and the aircraft industry. It was a compilation of data submitted by the services, the material suppliers and the industries own data.

On September 12, 1950, the "Tentative Requirements for Transparent Plastic Enclosure Materials" was released. This constituted the best list of needed requirements for monolithic materials that could be established by

the industry and was released as such to the services and material suppliers. This list also provided specific test methods for the evaluation of materials.

The new materials being made available prompted the ARTC to initiate a cooperative test program to evaluate these materials in accordance with certain of the tests specified in the list of requirements.

PURPOSE

(29)

This ~~particular~~ report presents the test requirements <sup>for aircraft glazing use</sup> for transparent materials and includes a summary of the industry's cooperative testing on a group of these materials. The materials tested included: Plex IA, Plex II, 5014XP, 5015XP, Sierracin 611, Polymer K, and HE 5621.

Tables of test data (<sup>probably</sup> ~~evidently~~ now obsolete) are included.]

AUTITOR, MODIFIED

REVISED TENTATIVE REQUIREMENTS FOR  
TRANSPARENT PLASTIC ENCLOSURE MATERIALS

- NOTE: (a) Following are the tentative requirements for transparent plastic enclosure materials as revised by the W-38 Subcommittee of the Aircraft Research & Testing Committee at meetings up to and including the one held May 13, 1952.
- (b) All specimens shall be annealed for 16 hours at 25°F below their average heat distortion temperature and cooled at a rate not to exceed 50°F per hour. Following annealing and immediately prior to test, all specimens shall be conditioned for 96 hours at 77 ± 2°F and 50 ± 5% R. H.

MONOLITHIC MATERIAL

- A. Optical Properties - The material shall have optical properties equal to or better than MIL-P-6886 acrylic. \*\*
- B. Heat Distortion Point - Material shall have a heat distortion point of 230°F when tested per ASTM D648-45T at 264 psi. Temperature rise shall be 2°C per minute. (This satisfies present requirements but a heat distortion point of 250°F will be needed in the near future.)
- C. Craze Resistance - The material shall have no tendency to craze or deteriorate under fiber stress of at least 4500\* psi with or without solvent action when tested in accordance with MIL-P-6997 except (1) a nominal .125 inch fulcrum radius shall be used, (2) the load shall be applied for ten minutes before addition of solvents, and (3) no crazing during the first five minutes of solvent application shall be apparent.

The solvents to be applied continuously shall be isopropyl alcohol and toluene per Specification TT-T-548. Crazing tests shall also be conducted in the same manner at 2000, 3000, 4000 and 5000 psi and the stress recorded at which crazing first appears.

- D. Tensile Strength - The material must have a tensile strength equal to or better than acrylic base plastics per MIL-P-6886.\*\* Tests shall be conducted per ASTM-D638-49T except wider modifications in the configuration and preparation of Type I specimens are to be allowed. These modifications are to be reported. The ultimate tensile strength after 2 hours at 230°F and tested at 230°F shall not be less than 4000\* psi.
- E. Flexural Strength - The material shall have a flexural strength of not less than 16,000\* psi when tested per ASTM-D790-45T or L-P-406a. Load deflection curves shall be obtained.
- F. Notch Sensitivity (scratched flexural) -
1. When tested per ASTM-D-790-45T with a scratch on the tensile side, the material shall have a flexural strength of 10,000\* psi or not less than 60%\* of un-notched ultimate strength at room temperature. Scratch or notch shall be .004 to .007 inches in depth normal to the specimen length in the center of the span extending to within 0.05 inches of either edge as made by a hardened steel scribe .250 inches in diameter, tapered to a point in the distance of one inch, point radius not to be more than .002 inches. Load deflection data shall be reported.
  2. The flexural strength at -65°F shall not be less than the room temperature strength. The specimen shall be conditioned for 24 hours at -65°F and tested at -65°F. Load deflection data shall be reported.

3. The notched flexural strength at 120°F shall be determined and reported.

G. Impact Test - Tests shall be in accordance with ASTM-D-256-41T with the following exceptions:

1. The cantilever beam (Izod type) test shall be used. Weight of the pendulum, scale graduations and construction shall be such as to provide a total range of at least 2 ft. lbs. readable to an accuracy of .02 ft. lbs.
2. The specimen shall be made from sheet stock of .250 nominal thickness and shall be  $.250 \pm .010$  thick by  $.500 \pm .000$  wide by  $2.50 \pm .100$  long. At least one surface shall be left in the as-manufactured condition. Machined surfaces within the central inch of the specimen length shall be smooth-finished with 400 grit abrasive or finer. No polishing is permitted on the as-manufactured surface. The specimen must not be overheated in preparation.
3. The specimen shall be mounted flatwise in the clamps of the impact machine so that the pendulum strikes across the thickness dimension causing tension in the as-manufactured surface.
4. Notched specimens shall be prepared by placing the scratch in the tension (as manufactured) surface at the centerline of the specimen and extending across the .500 inch dimension to within .05 inches of either edge. The scratch shall be  $.004 - .007$  deep, made with a hardened steel scribe .250 inches in diameter tapered to a point in the distance of 1 inch, point radius not to exceed .002 inches. The notched specimen shall be mounted so that the distance from the scratch to the level of the top of the clamping surface is  $.000 - .010$  inches.

5. Tests shall be conducted at room temperature and at  $-65^{\circ}\text{F}$ .
6. Test Values - Impact test values averaged from a group of five, shall not be less than indicated below. Individual test values shall not deviate more than 20% from the average. Desired values are the same for room temperature and for  $-65^{\circ}\text{F}$ .

Plain Specimen	1.5 ft./lbs.	* per inch of width
Notched Specimen	.5	*

H. Elevated Temperature Creep Tests - When subjected to four of the temperature-stress cycles described under paragraphs 1 through 8 below, .25 inch thick tensile test specimens, prepared as per Specification LP-406a Method 1011 (Type I Specimens), shall not exhibit more than 3 per cent\* permanent extension between gage marks. Cycle specimens as follows:

1. Place test specimens in a circulating air oven at  $230 \pm 3^{\circ}\text{F}$  for one hour at zero load.
2. Maintaining the test specimen at  $230 \pm 3^{\circ}\text{F}$  apply a tensile stress of 600 psi for one hour.
3. Remove the tensile stress and allow specimen to remain unloaded at  $230 \pm 3^{\circ}\text{F}$  for one hour.
4. Repeat steps 2 and 3 two additional times.
5. Maintaining the test specimen at  $230 \pm 3^{\circ}\text{F}$  apply a tensile stress of 600 psi for one hour.
6. After the one hour loading period and while maintaining the test specimen under the 600 psi stress at  $230 \pm 3^{\circ}\text{F}$ ., determine the maximum extension.

7. Unload the specimen and allow it to cool at room temperature and stand unloaded for 16 hours.
  8. Determine the permanent extension at room temperature at zero load after the 16 hour unloaded period.
  9. One temperature-stress cycle consists of steps 1 through 8 inclusive. Extension at load and at no load for each cycle shall be recorded.
- I. 10,000 Hour Flexural Strength Requirements: (Tentative) Material shall have 10,000 hour flexural strength of 3000\* psi without crazing or deterioration when determined by the following method:
1. Test shall be conducted per ASTM-D790-45T using .250 material, except the specimen shall have a standard scratch per the short time notched bending test. Test conditions shall be  $50 \pm 5\%$  R.H. and  $75 \pm 5^\circ\text{F}$  temperature. Three specimens shall be loaded to 50% ultimate stress determined from the short time notched bending test, three loaded at 60%\* ultimate and three at 80%\* ultimate. Record the initial deflection of each specimen and the creep each 24 hours. Also record the time of failure in hours.
  2. Plot the results on log-log graph paper with the ordinates representing hours and the abscissae maximum fiber stress in bending as calculated by the simple beam formula. Place a point for the short time ultimate stress on the ordinate representing 0.1 hour, and place points for the time of failure in hours of 50, 60 and 80% ultimate stress specimens on their proper ordinates. Draw a straight line between the short time ultimate stress point and the center of the group of points obtained from loads less

than ultimate. Extend this line to the ordinate 10,000 hours and record the stress allowable at that point. This stress shall be considered the 10,000 hour flexural strength.

#### J. Weathering Tests

Test arrangement and conditions shall be in accordance with ASTM-D674-42T with the following exceptions:

1. Minor modifications are permitted in the shape of the specimen to insure proper gripping and uniform loading within the test length. Suitable specimens and grips are shown in attached figures 1 and 2 (pages 14 and 15). Deviations from these specifications are to be reported.
2. The specimen shall be made of standard sheet product, and the as-manufactured surfaces shall be free of scratches and not disturbed during fabrication of the specimen.
3. Materials need not be classified into groups of materials. Extensometers and deformation measurements are not required. Gage marks shall not be made on the specimen.
4. Duplicate specimens shall be tested at constant stresses of 1. 2000 psi, 2. 4000 psi and 3. 6000 psi.
5. The test shall be conducted under exposure condition, in a region where incident sunlight under clear sky conditions would be unobstructed for at least 60%\* of the daylight hours. Protection from ground winds and artificial disturbances is desired.
6. Observations shall be made and reported of the nature and time required for any kind of deterioration, and the total time until fracture occurs.

7. Simultaneous tests shall be conducted on the unknown material and on MIL-P-6886 acrylic material to establish a basis for comparison. Requirements are as follows:

The average "life-time" under 4000 psi shall be in excess of the average time for fracture of MIL-P-6886 acrylic at 4000 psi.

The average "life-time" under 6000 psi shall be in excess of the average time for fracture of MIL-P-6886 acrylic at 4000 psi.

"Life-time" is defined as the time required to produce any objectionable discoloration, deterioration, or crazing discernible under the most critical lighting conditions, within the test length.

- K. Forming - Material shall be capable of being formed to a spherical segment as follows: 1/4 thick sheet, 1 ft. in diameter shall be capable of being drawn to a depth of 3 inches for canopies and 6 inches for domes.

In conducting the forming tests fixed clamping shall be used and no slippage shall occur. Depth of draw at forming pressures of 3, 6, 9, 12, psi and higher pressures if necessary and forming procedure and temperatures shall be reported. Exceptions to the above requirements will be allowed for those applications which do not require high temperature performance, high degree of forming, etc.

- L. Hardness - The material at room temperature shall have a minimum hardness value of 35 when determined by the Barcol impressor.

- M. Joining - The material shall be capable of being joined by conventional cementing procedures and a minimum bond strength of 3500\* psi shall be required when tested in accordance with the test for Bond Strength of Monolithic Transparent Enclosure Materials (Enclosure D, Minutes of June 11 and 12, 1951, Meeting, ARTC-WR-51-87 July 17, 1951). Test is outlined on pages 16 through 24.
- N. Flammability - It is desirable that the burning rate does not exceed that of MIL-P-6886\*\* acrylic.
- O. Water Absorption - The water absorption shall not exceed that of MIL-P-6886\*\* acrylic.
- P. Coefficient of Thermal Expansion - The coefficient of thermal expansion shall not be greater than, and it is desirable that it be less than MIL-P-6886\*\* acrylic.

#### LAMINATED MATERIAL

- Note: (a) All tests shall be conducted on a standard laminate having .150 faces and .20 interlayer, and tensile values shall be based on the face sheet area only.
- (b) Heat stability tests shall be performed on all material prior to test.

#### A. Heat Stability and Forming

##### 1. Heat Stability:

- 1.1 Requirements: After heating for one half hour, as described in paragraph 1.2 below, the laminated sheet shall conform to the physical property requirements defined in this specification.

1.2 Test Procedure:

1.2.1 A test specimen of the laminated sheet, minimum four square inches, shall be hung vertically in a circulating air oven stabilized at temperature referred to in paragraph A-2 below.

1.2.2 After heating one half hour, the test specimen shall be removed from the oven, cooled at room temperature at a rate not to exceed 50°F per hour.

2. Forming Temperature Range: The manufacturer shall define the processes and forming temperature range to be used in forming parts. The forming temperature range is defined as the difference between the maximum and minimum temperatures that may be used in the forming process without deleteriously affecting the laminated sheet. The forming temperature range shall not be less than 20°F.

3. Forming Requirements: This requirement covers three different grades of laminated sheet with respect to forming properties (i.e., sheet usable for forming (1) Shallow Drawn Shapes, (2) Deep Drawn Shapes, and (3) Single Curvature Shapes).

3.1 Shallow Drawn Shapes (Canopies)

The laminated sheet shall be capable of being drawn to a depth of 2 inches when formed through a 14 inch diameter ring. The sheet shall also be capable of being formed into a single curvature shape with a radius of 7 inches.

3.2 Deep Drawn Shapes (Domes): The laminated sheet shall be capable of being formed into a hemisphere with a radius of 7 inches.

- 3.3 Single Curvature Shapes (Windows): The laminated sheet shall be capable of being formed into a single curvature shape with a radius of 20".

B. Optics

1. Original Haze - The haze in the as-received condition shall be no greater than 4.0% when measured in accordance with the test for Visible Light Transmission and Haze, Method 3021, of Specification L-P-406a.
2. Minor Optical Defects - The total number of minor defects shall not exceed three per four square feet and all minor defects shall be at least six inches apart. Minor defects include any imbedded particles, streaks, orange peel, bubbles, or scratches which reduce visibility through the plastic. Blemishes which do not individually reduce visibility through the plastic shall be disregarded. Defects within one inch of the edge of the sheet shall be disregarded. Inclusions such as lint, hair, and dust particles shall not be considered blemishes unless they individually affect an area greater than that equal to the area of a circle with a diameter of 0.20 inches. Splices in the interlayer will be allowed.
3. Angular Deviation - The material shall contain no variations which cause an angular deviation of more than 8 minutes either side of the undeviated position. The movement of the image shall not be irregular or wavy. The angular deviation shall be determined in accordance with the test method for Optical Uniformity, Method 3041 of Specification L-P-406a.

4. Optical Distortion - The optical distortion value of the material shall be no less than 12 inches excluding a margin of two inches when tested in accordance with Optical Uniformity, Method 3041 of Specimen L-P-406a.

- C. Fracture Resistance at Low Temperature - A specimen approximately eight square inches in area shall be cooled to  $-18^{\circ} \pm 2^{\circ}\text{C}$  ( $0 \pm 4^{\circ}\text{F}$ ) for sufficient time to insure equilibrium temperature throughout the laminate. The specimen shall be placed on a rigid flat surface with the geometric center of the specimen over a 1/2 inch diameter hole in the flat surface and immediately struck near the geometric center with a one pound ball dropped from a height of 8 feet. If both layers of the face sheet are not fractured, the specimen shall be turned over and struck again with the same force.

After fracture at low temperature in accordance with the above test, the test specimen shall show no delamination from any crack in the face sheet material.

D. Long Time Tensile Test

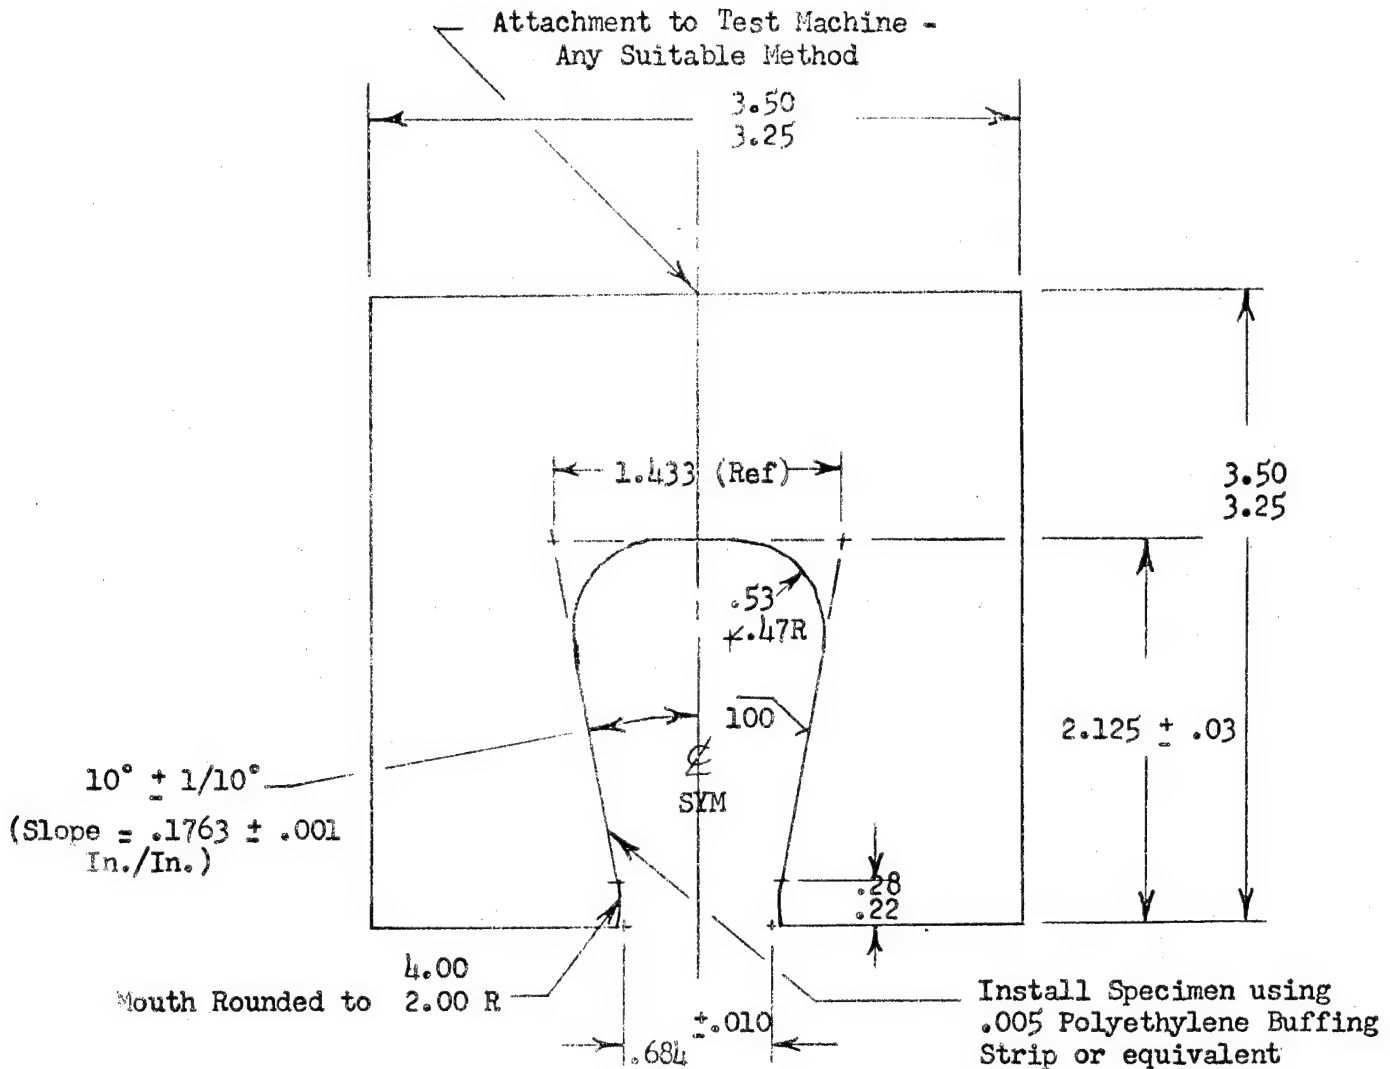

Test arrangement and conditions shall be in accordance with ASTM D674-48, with the following exceptions:

1. Minor modification is permitted in the shape of the specimen to insure proper gripping and uniform loading within the test length. Suitable specimen and grip configuration Fig. I and II respectively (pages 14 and 15). Deviations from these specifications are to be reported.

2. The specimen shall be made from standard sheet product. The as-manufactured surfaces shall be kept free of scratches and undisturbed during the fabrication of the specimen.
3. Machining of the specimen shall be accomplished with cutters and speeds which introduce no local heating or surface effects into the specimen. Generally recommended is a small diameter router cutter turning at high speed, but traversing slowly; best combination of speeds and cutter face angles should be determined for the particular test material. If necessary, specimens should be finished with 400 sandpaper and polished. Polariscopic examination can sometimes be used to check for strains by the machining operations.
4. Machined edges of the specimen which remain exposed after installation in the test grips shall be coated with EC 226 cement (Minnesota Mining & Manufacturing Company) and allowed to dry for 24 hours before loading.
5. Measurement of elongation is not required. No gage marks shall be made on the specimen.
6. Specimens shall be tested at constant stresses of 1,000, 2,000, 4,000 and/or 6,000 psi.
7. The tests shall be conducted under outside exposure conditions in an area where incident sunlight under a clear sky would be unobstructed for at least 60% of the daylight hours. Protection from ground winds and artificial disturbances is desired.
8. Observations shall be made to determine the time for crazing to be initiated, the time to failure, and any unusual behavior during the test.

## TENTATIVE SPECIFICATION FOR TESTING BOND STRENGTH OF TRANSPARENT PLASTIC

### ENCLOSURE MATERIALS

#### 1. Scope

- 1.1 This specification describes a test procedure for determining the bond strength, based on compression shear, of monolithic transparent plastic enclosure materials.

#### 2. Test Specimen

- 2.1 The nominal specimen configuration shall be as shown in Figure 1.

#### 3. Apparatus

- 3.1 The test jig used shall be as shown in Figures 2, to 7 (pages 18 to 24).
- 3.2 All tests shall be conducted on a standard universal testing machine of suitable capacity.

#### 4. Procedure

##### 4.1 Preparation of control specimens

- 4.1.1 When required, five control specimens shall be made to conform to Figure 1, and shall be made of Plexiglas II, Specification MIL-P-5425.
- 4.1.2 Soak cemented joints shall be prepared from 0.250 Plexiglas II strips milled to one inch widths. Except for the areas to be jointed, the strips shall be masked with cellophane tape. One joint half shall be soaked for 17 minutes in acrylic monomer base cement, Specification No. AN-C-141 (catalyzed with 0.4 grams per pound of crystalline

benzoyl peroxide) and placed into position over the remaining joint half. The two joint halves shall be held together with a pressure of approximately 5 psi for a minimum of 24 hours. Following this the joints are to be heat cured for 24 hours at  $120 \pm 5^{\circ}\text{F}$  before being sawed and milled to the configuration shown in Figure 1.

#### 4.2 Preparation of Test Specimens

4.2.1 Five test specimens shall be prepared from 1 inch milled strips of the material under consideration, and shall conform to Figure 1.

4.2.2 When applicable, specimens shall be prepared in a manner similar to the control specimens Par. 4.1.2. For other materials joints shall be made with suitable cements and in accordance with the manufacturer's instructions.

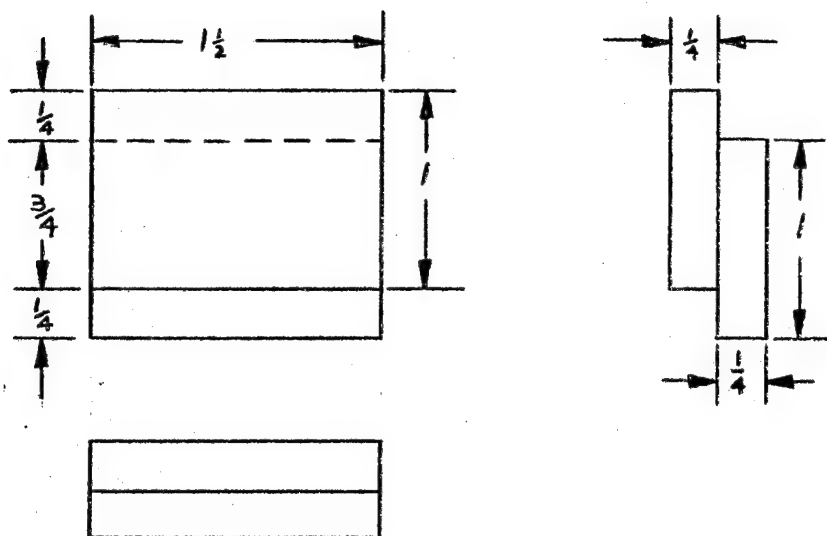

#### 4.3 Testing of Specimens

4.3.1 Specimens shall be accurately measured and then tested by using the test jig shown in Figure 2. The specimens shall be placed in the jig, and the testing machine started. The head travel shall be adjusted to  $0.05 \pm 25\%$  inches per minutes, and shall be maintained until the specimen ruptures.

### 5. Test Data

5.1 The test report shall include the following data:

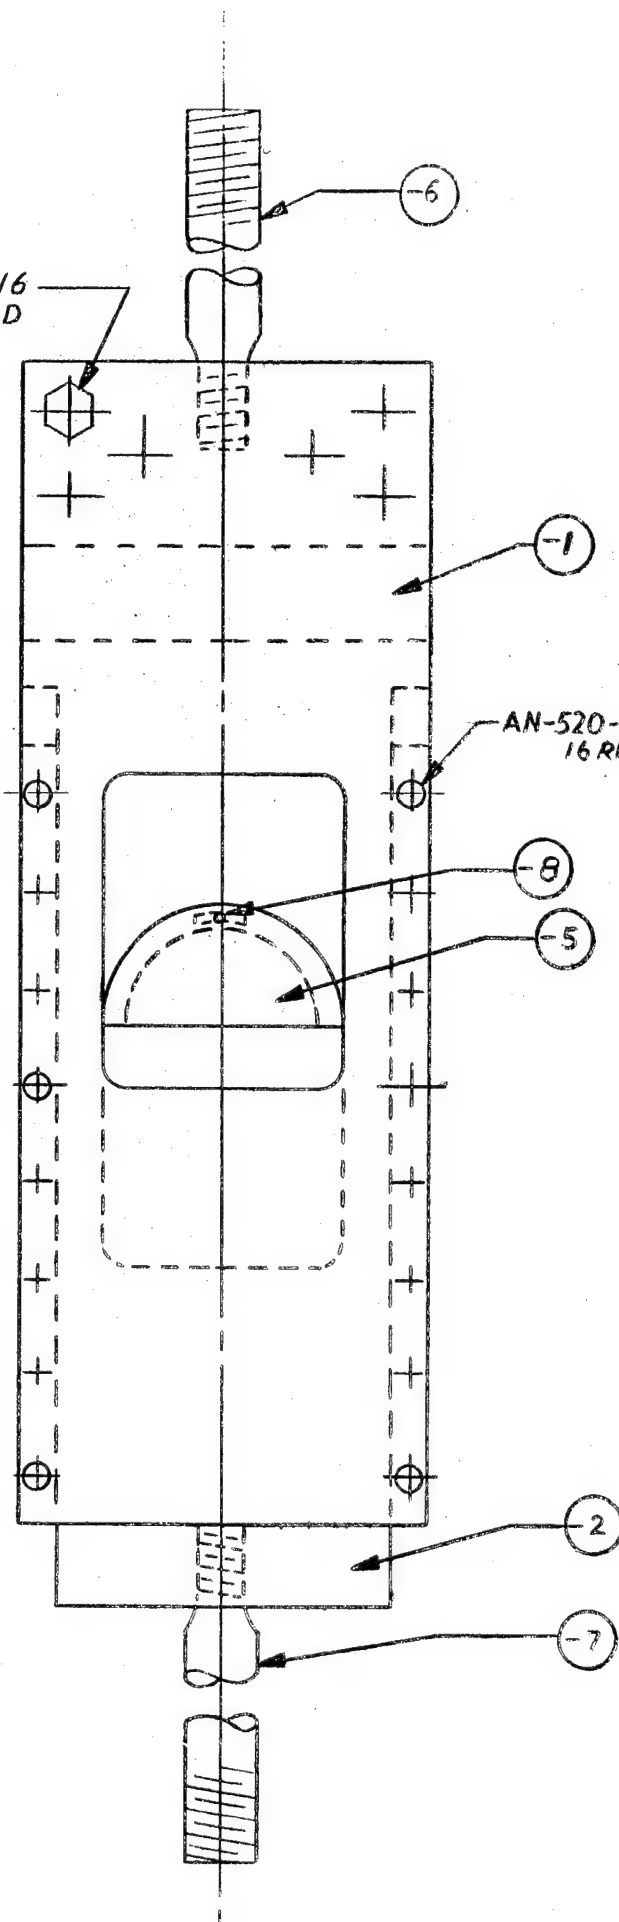

- 5.1.1 Type of material and manufacturer's designation.
- 5.1.2 The cement and procedure used for bonding the material.
- 5.1.3 The results of the five control specimens and the average result expressed in pounds per square inches of shear.
- 5.1.4 The results of the five specimens under consideration and the average result expressed in pounds per square inch of shear.

## GENERAL NOTES ON TEST RESULTS

1. On data sheets the following abbreviations are used in "Source of Data" columns:

B - Boeing Airplane Company

D - Douglas Aircraft Company

L - Lockheed Aircraft Corporation

N. A. - North American Aviation, Inc.

Nor. - Northrop Aircraft, Inc.

2. The 10,000 hour flexural strength values as represented on the long time flexural graphs are not absolute because of the spread of plotted time values at 50, 60, 80 and 100% of ultimate stress, it is possible to vary the slopes of the straight lines thus obtaining different intersections with 10,000 hour ordinates.

- (1) All Lockheed crazing data was recorded to the nearest minute and obtained per LAC Specification 1-848.
- (2) Light Craze
- (3) One specimen did not craze until load was momentarily reapplied.
- (4) Pronounced Craze
- (5) Sheet "A"
- (6) Sheet "B"
- (7) One specimen did not craze
- (8) Specimen failed
- (9) One specimen failed on preload

# FORMING

6" Diameter Hemispherical Shape.  
Using Air-pressure Fixture.

<u>3" Depth Draw</u>	Temperature, °F.				
	<u>275</u>	<u>300</u>	<u>325</u>	<u>350</u>	<u>375</u>
Air-Pressure, P.S.I.					
Plexiglas II Thickness, In.	30 (.271)	20 (.235)	18 (.276)	17 (.266)	15 (.278)
MACA Thickness, In.	-	-	20 (.231)	18 (.263)	10 (.232)
Plexiglas 5105 Thickness, In.	-	26 (.254)	19 (.231)	19 (.231)	18 (.231)

## Various Draw Depths at 275°F

Plexiglas 5105	.254" Thickness	1-1/2" Draw	20 P.S.I.
	.254" "	2" Draw	30 P.S.I.
	.254" "	2-5/8" Draw	32 P.S.I.
	.244" "	2-3/4" Draw	36 P.S.I.
Sierracin 611	.251" "	1/2" Draw	22 P.S.I.
	.253" "	1/2" Draw	24 P.S.I.

- Note 1. -Marks indicate conditions under which the sheet tested was obviously too rigid.
2. MACA - Methylalpha-Chloro-Acrylate.
3. Sierracin 611 = Selectron 44.
4. Sierracin 611 sheets broke at 275°F:
- a. Three, under 10 to 40 P.S.I. air-pressure.
- b. Two, using male plug and manual load application.

## Results of Cementing Tests of Transparent Plastics

Source: Convair - San Diego

### Specimen:

Compression shear type specimens consisted of two milled strips of transparent material 1" x 8" x .250" overlapped in bonding by 3/4 inch to form bonded pads 1-1/4" x 8" which were cut into test specimens 1 inch wide.

### Bonding Procedure

Plexiglas II was prepared by masking with cellophane tape and dipping one milled strip in ethylene dichloride for 17 minutes. The masking tape was removed and the soaked strip was placed in position over the unsoaked strip with a 3/4" overlap. The two joint halves were then bonded 30 hours with a pressure of 5 psi.

Sierracin, 5105 XP, and Gafite bonds were all prepared with Epon Adhesive VI. Faying surfaces were cleaned thoroughly with Fullercol (Denatured Ethyl Alcohol). The adhesive was then applied to both bonding surfaces and the strips were placed in position with contact pressure only, (approximately 1-2 psi). All specimens were allowed to cure at room temperature for 24 hours.

### Annealing Procedure

Specimens were annealed as follows prior to test:

Plexiglas II	120° + 2°F for 20 hours
Sierracin 611	175° + 2°F for 20 hours
Rohm & Haas 5105 XP	190° + 2°F for 20 hours
General Analine Gafite (MACA)	250° + 2°F for 20 hours

### Conditioning Specimens

All specimens were conditioned prior to test for 96 hours at 77°F ± 2°F and 50 ± 5% relative humidity.

### Results

Results in terms of pounds per sq. in. in compressive shear are tabulated below.

<u>Spec. No.</u>	<u>Plexiglas II</u>	<u>5105 XP</u>	<u>Sierracin 611</u>	<u>Gafite (MACA)</u>
1	3390	4800	3420	3990
